Abstract

In the paper locally superquadratically convergent methods for minimization functions are considered. Threefold symmetric approximations to partial derivatives of the third order are constructed.

1. Introduction

Let $f: D \subset R^n \rightarrow R$, $f \in C^3(D)$, D - open set. We want to find $x^* \in D$ such that $\nabla f(x^*) = 0$. For a given $x_0 \in D$ the Newton method defines the sequence $\{x_k\}$ in the following way

$$\nabla^2 f(x_k) s_k = -\nabla f(x_k), \quad x_{k+1} = x_k + s_k, \quad k = 0, 1, 2, \dots \quad (1)$$

If the matrix $\nabla^2 f(x^*)$ is nonsingular then Newton method is locally quadratically convergent to x^* , i.e. there exist $c > 0$ and $\varepsilon > 0$ such that, if $\|x^* - x_0\| < \varepsilon$, then

$$\|x_{k+1} - x^*\| \leq c \|x_k - x^*\|^2. \quad (2)$$

To assure global convergence of the method one should consider a sequence

$$x_{k+1} = x_k + t_k s_k, \quad t_k \in R, \quad k = 0, 1, 2, \dots \quad (3)$$

and the parameter t_k should satisfy the global convergence conditions. If the matrix $\nabla^2 f(x^*)$ is singular, then the Newton method is divergent or at most linearly convergent to x^* . To assure a great speed of convergence for singular problems one applies the method of the third rate of convergence: for a given $x_0 \in D$ the sequence $\{x_k\}$ is defined as

$$x_{k+1} = x_k + s_k, \quad k = 0, 1, 2, \dots \quad (4)$$

* Corresponding author: *e-mail address:* s.grzegorski@pollub.pl

where s_k is the solution of the system of quadratic equations

$$\nabla f(x_k) + \nabla^2 f(x_k) s_k + \frac{1}{2} (\nabla^3 f(x_k) s_k, s_k) = 0. \quad (5)$$

When the calculation of the operator $\nabla^3 f(x_k)$ is too expensive or is not attainable for computation then we propose a new class of the methods which are locally superquadratically convergent to x^* , i.e.

$$\lim_{k \rightarrow \infty} \frac{\|x_{k+1} - x^*\|}{\|x_k - x^*\|^2} = 0. \quad (6)$$

Let $B_k = (B_k^1, B_k^2, \dots, B_k^n)$, $B_k^i \in R^{n \times n}$, $B_k^i = (B_k^i)^T$, $i = 1, 2, \dots, n$. The sequence $\{x_k\}$ is defined by (1.4) and

$$\nabla f(x_k) + \nabla^2 f(x_k) s_k + \frac{1}{2} (B_k s_k, s_k) = 0. \quad (7)$$

If the problem $\min_{x \in D} f(x)$ is regularly singular at x^* , i.e.

$$\det(\nabla^2 f(x^*)) = 0, \text{ and } \|\nabla f(x)\| \geq c \|x - x^*\|^2, \quad c > 0, \quad x \in D, \quad (8)$$

then the sequence $\{x_k\}$ defined by (1.4) and (1.7) is locally superlinearly convergent to x^* , if the operators B_k are constructed in an adequate way. In this paper such algorithms are given.

2. The BFGS method

The DFP (Davidon [1], Fletcher and Powell [2]) method is very well known as the method of approximation to the Hessian $\nabla^2 f(x_k)$. This formula has the form

$$B_{k+1} = B_k - \frac{B_k s_k s_k^T B_k}{s_k^T B_k s_k} + \frac{y_k y_k^T}{y_k^T s_k}, \quad y_k = \nabla f(x_{k+1}) - \nabla f(x_k). \quad (9)$$

The DFP formula, for nonsingular problems, guarantees local superlinear convergence of the method

$$x_{k+1} = x_k + s_k, \quad B_k s_k = -\nabla f(x_k), \quad k = 0, 1, 2, \dots \quad (10)$$

We may use the DFP formula to approximate the operator $\nabla^3 f(x_k)$. Namely, let

$$B_k = (B_k^1, B_k^2, \dots, B_k^n), \quad B_k^i \in R^{n \times n}, \quad B_k^i = (B_k^i)^T, \quad i = 1, 2, \dots, n \quad (11)$$

and let $\nabla_i^2 f(x_k)$ denote i-th column of the matrix $\nabla^2 f(x_k)$,

$$y_k^i = \nabla_i^2 f(x_{k+1}) - \nabla_i^2 f(x_k). \quad \text{Then}$$

$$B_{k+1}^i = B_k^i - \frac{B_k^i s_k s_k^T B_k^i}{s_k^T B_k^i s_k} + \frac{y_k^i (y_k^i)^T}{(y_k^i)^T s_k}, \quad i = 1, 2, \dots, n. \quad (12)$$

Note that the operators B_{k+1} satisfy the equation

$$B_{k+1}s_k = \nabla^2 f(x_{k+1}) - \nabla^2 f(x_k), \quad k = 0, 1, 2, \dots \quad (13)$$

Now, from the general theory for the systems of nonlinear equations [3], [4] local superquadratic convergence of the method results (4), (7) with the update (12). On the other hand, the DFP updates do not satisfy the following properties of the partial derivatives

$$\frac{\partial^3 f(x)}{\partial x_i \partial x_j \partial x_l} = \frac{\partial^3 f(x)}{\partial x_i \partial x_l \partial x_j} = \dots = \frac{\partial^3 f(x)}{\partial x_l \partial x_j \partial x_i}, \quad i, j, l = 1, 2, \dots, n. \quad (14)$$

In this case, we say the operator $\nabla^3 f(x)$ is threefold symmetric (T-symmetric).

It is worth remarking that the operator $\nabla^3 f(x)$ has only $P(n) = \frac{1}{6}n(n+1)(n+2)$

different elements and the DFP approximations have $Q(n) = \frac{1}{2}n^2(n+1)$ different elements, which means that the BFGS formula is not adequate for approximation to $\nabla^3 f(x)$. In the next Section we give a new formula for the update of B_k and B_k will be T-symmetric.

3. New approximation to $\nabla^3 f(x)$

The approximation B_k to $\nabla^3 f(x)$ satisfies secant equation (13) and operators B_k should be threefold symmetric. If we take

$$B_{k+1} = B_k + E, \quad (15)$$

then

$$E s_k = \nabla^2 f(x_{k+1}) - \nabla^2 f(x_k) - B_k s_k = Y. \quad (16)$$

In that case we have to solve the problem

$$\min \|E\|^2, \quad \|E\|^2 = \sum_{i=1}^n \sum_{j=1}^n \sum_{k=1}^n E_{ijk}^2 \quad (17)$$

under constraints

$$E s = Y, \quad s \in R^n, \quad Y \in R^{n \times n}, \quad Y = Y^T \quad (18)$$

and

$$E_{ijk} = E_{ikj} = E_{jik} = E_{jki} = E_{kij} = E_{kji}, \quad i, j, k = 1, 2, \dots, n. \quad (19)$$

Remark. If we take another norm of the operator E , then we get another formula for the update B_k .

Let $\Lambda \in R^{n \times n}$. In our case the lagrangian has the form

$$L(E, \Lambda) = \frac{1}{2} \|E\|^2 + \sum_{i=1}^n \sum_{j=1}^n \Lambda_{ij} \left(\sum_{k=1}^n E_{ijk} s_k - Y_{ij} \right). \quad (20)$$

From this we have

$$\frac{\partial L(E, \Lambda)}{\partial E_{pqr}} = E_{pqr} + \Lambda_{pq}s_r = 0. \quad (21)$$

The fact $E_{pqr} = E_{qpr}$ implies $\Lambda = \Lambda^T$. Since the operator E is threefold symmetric then equation (21) may be written as

$$E_{pqr} = -\frac{1}{3}(\Lambda_{pq}s_r + \Lambda_{pr}s_q + \Lambda_{qr}s_p) \text{ for } 1 \leq p \leq q \leq r \leq n. \quad (22)$$

Now, the equation $Es = Y$ has the form

$$\sum_{l=1}^n (\Lambda_{ij}s_l + \Lambda_{il}s_j + \Lambda_{jl}s_i)s_l = -3Y_{ij} \quad 1 \leq i \leq j \leq n \quad (23)$$

or is in the matrix form

$$\Lambda \|s\|^2 + \Lambda ss^T + ss^T \Lambda = -3Y. \quad (24)$$

Therefore

$$s^T \Lambda s = -\frac{1}{\|s\|^2} s^T Y s, \quad u = \Lambda s = \frac{1}{2\|s\|^2} (-3Ys + \frac{s^T Y s}{\|s\|^2} s). \quad (25)$$

Finally

$$\Lambda = -\frac{1}{\|s\|^2} (3Y + us^T + su^T). \quad (26)$$

To calculate the new threefold symmetric update $B_{k+1} = B_k + E$ we use the formulae (22), (25) and (26).

4. Remarks on the local superquadratic convergence of the method

At first we describe the proposed algorithm:

- Let $x_0 \in R^n$ and $B_0 = (B_0^1, B_0^2, \dots, B_0^n)$ - threefold operator be given. Let $k = 0$,
- Solve, using for example the Newton method, the system of quadratic equations

$$\nabla f(x_k) + \nabla^2 f(x_k)s_k + \frac{1}{2}(B_k s_k, s_k) = 0,$$

- Calculate $x_{k+1} = x_k + s_k$, $\nabla f(x_{k+1})$, $\nabla^2 f(x_{k+1})$,
- Update the operator B_k using the formulae from Section 3,
- If a stop criterion is not satisfied, then $k := k + 1$ and return to point b.

To explain a character of convergence of the method we introduce some notations. Let

$$H_k = \int_0^1 \nabla^3 f(x_k + t(x_{k+1} - x_k)) dt , \quad (27)$$

$$L_k = \{X \in R^{n \times n \times n} : X s_k = \nabla^2 f(x_{k+1}) - \nabla^2 f(x_k)\} , \quad (28)$$

$$Q = \{X \in R^{n \times n \times n} : X \text{ is threefold symmetric operator}\} . \quad (29)$$

The set Q is linear subspace in $R^{n \times n \times n}$ and $H_k \in Q$. Applying Theorem 3.2.7 [5] we have

$$H_k s_k = \nabla^2 f(x_{k+1}) - \nabla^2 f(x_k) , \quad (30)$$

which means that $Q \cap L_k$ is a nonempty linear set. The proposed norm is generated by inner product, so the operator B_{k+1} is defined as the orthogonal projection of the operator B_k onto the set $Q \cap L_k$, and from Pitagoras Theorem (see [3]) we get

$$\|B_{k+1} - H_k\|^2 + \|B_k - B_{k+1}\|^2 = \|B_k - H_k\|^2 \quad k = 0, 1, 2, \dots \quad (31)$$

The inequality $\|B_{k+1} - H_k\| \leq \|B_k - H_k\|$ implies local linear convergence of the sequence $\{x_k\}$. From equations (31) it results additionally

$$\sum_{k=0}^{\infty} \|B_{k+1} - B_k\|^2 < \infty . \quad (32)$$

The last inequality and the secant equation (13) assure local superquadratic convergence of the proposed algorithm [4].
